

LIFE CYCLE ASSESSMENT-THE FIRST STEP TOWARDS SUSTAINABILITY

**Tim
Cole**

Summary

Facility managers have a direct impact on the health and wellbeing of every person that steps into their building. In addition, they have an impact on the life-cycle costs of buildings. Like many organizations, environmental responsibility is a core value they possess. One of the truest measures of environmental performance is the LCA, Life-Cycle Assessment. Life Cycle is a tool that is used to evaluate a variety of a product, process or corporate issue in which environmental improvement is being made. LCA's help you to do your job better by allowing an organization to see which products directly and positively affect the health and wellbeing of every person that walks inside your door.

Keywords: Life cycle assessment, green wash, sustainability, environmental impact

1 Introduction

Have you ever stopped to consider what exactly it is that you do? As the title facility manager suggests, you manage the facility. Many within the industry see their responsibilities as those that ensure their building or buildings run properly. And while that's true, it's just the tip of the iceberg. As facility managers, you have a direct impact on the health and wellbeing of every single person who walks through your front door. The decisions you make and the products you buy can improve or degrade the long-term health of your building and its occupants. They can also have a profound impact on the life-cycle costs of the buildings.

How do you select which products you are going to buy and which ones you won't? When you consider that most everyone within the walls of your facility are there for more than one third of the day and that nearly 75 % of corporate expenditures is on employee salaries and benefits, only then do you begin to fully understand the enormous impact that the decisions you make have on the financial success of your company. You can increase productivity, reduce absenteeism and improve the overall health of your building's occupants... just by making the right decisions every day. But where do you start?

2 Sustainable Products

Green products and even entire green buildings have slowly made their way into the general public. Europe has been ahead of the curve in this arena and international organizations, such as Forbo have benefited from it. But what makes a product green? Are there specific guidelines or standards? The answer is, “No yet,” but they are coming soon... but not soon enough. There are several products available making claims that, while true, may be misleading.

This practice has led to the term “Greenwash.” Greenwash is the tide of unsubstantiated green claims that are made by companies and brands that do little more than confuse their customers. And it is the most dangerous obstacle that you, the facility manager, need to overcome in order to make the best informed decisions.

Sustainable products are those products providing environmental, social and economic benefits while protecting public health, welfare, and environment over their full commercial cycle, from the extraction of raw materials to final disposition.

2.1 Sustainable Development

Society is becoming increasingly aware of the need for “sustainable development,” a term first used in 1987 by the United Nations-Chartered Brundtland Commission on Environment and Development.

- Agenda 21, developed and approved by the United Nations Conferences on the Environment held in Stockholm in 1972, in Rio de Janeiro in 1992 and Kyoto, Japan in 1997.
- Special conferences on Global warming held in 2000 in The Hague and in 2001 in Berlin.
- ISO-14001 environmental management systems.
- Local government certifications of production facilities.
- Benchmarking by independently done, peer-reviewed Life Cycle Assessment (LCA) Studies.
- Independent Environmental Certifications.
- The recommendations of experts.

2.2 Life Cycle Assessment

One of the truest measures of environmental performance is LCA, Life-Cycle Assessment

- To establish leadership in a demanding, emerging framework for environmental policy
- To quantify environmental input to engineering, materials, and product innovations
- To explore new advantages from evolving global environmental expectations
- To create parallel information to Cost of Ownership analyses.

There are a number of reasons to initiate an LCA, among them are:

- Response to sustainability metrics (rating or labeling systems)
- Engineering process and product improvements
- Database
- Positive, technical profile when meeting customer needs

Life cycle is a tool or technology, such as Six Sigma or Statistical Quality Control. LCA's are increasingly used to evaluate a variety of product, process, and corporate issues in which environmental improvement is being made, often referred to as an advanced environmental framework.

- Green purchasing
- Beneficial reuse options, both internally and externally
- International labeling or US rating systems
- Demand for recycle content from consumers
- Corporate sustainability policies
- CO₂ (or other emissions) trading credits
- Challenges of landfill shortages over the long-term
- European and Japanese government initiatives to require full life cycle responsibilities

3 Environmental Responsibility

Like many organizations, including companies within the Alliance for Sustainable Built Environments, environmental responsibility is a core value of Forbo, and has been for decades. We believe that being environmentally responsible is both the right thing to do as a corporate citizen, and the right thing to do for our business. We do not look at investments to improve our environmental performance as a “cost of doing business,” but rather an “investment for our future.”

We commit ourselves to overall standards and targets agreed upon with the government, but are free to determine how best to achieve them. The results of our efforts are published annually in a corporate environmental report. These reports are overviews of our environmental impact.

3.1 Environmental Responsibility and Life Cycle Assessment

The environmental impact of floor coverings can best be measured by carrying out a Life Cycle Assessment (LCA). LCA's chart the environmental impacts of a product 'from cradle to grave,' with equal weight given to all relevant issues. The use of LCA encompasses all elements and environmental impacts that are legitimately measurable.

Process elements include:

- raw material extraction and transport
- pre-processing
- production
- distribution
- installation
- use
- maintenance
- recycling and disposal

We believe an independently done, peer-reviewed LCA is the best benchmark to measure attained goals and to pinpoint focal areas to set new priorities. The science of doing LCA's has continually evolved and we always integrate the most recent technology and knowledge into the assessment.

The first steps of any analysis is to define the system boundaries, the functional unit (this is your unit of comparison), data requirements, alternative products or services you may want to compare, what key assumptions are you making, what are the likely limitations?

- What benefits are anticipated?
- How will the results be used?
- Who will have access to the results?
- If you don't come up with the "right" answer what will you do?

This can be difficult as it may be hard to get good reliable data. You need to carry out data quality assessments. It may be hard to get the information that you need from your competitors if you want to do comparative studies.

Data gaps

No process data was available for the following processes:

- The production and transport of pesticides (use and emission of pesticides is included.)
- The production and transport of some raw materials needed for maintenance products (additives, thickeners, solvents) and almost all ingredients for those materials.
- The production and transport of some raw materials needed for the production of materials used during laying (adhesives and materials used to seal the seams of professionally used linoleum floors.)
- The production and transport of a catalyst needed in the process "esterification of tall oil."

Results of life-cycle inventory are only as good as the data. Decide on the relative importance of environmental burdens and resource depletion.

Environmental impacts include:

- global warming
- embodied energy
- eutrophication
- natural resource depletion
- solid waste
- indoor air quality
- acidification
- ozone depletion
- smog formation
- ecological toxicity
- human toxicity

The cumulative combination of these factors defines the LCA for a product. It is important to note that LCA methods are product specific, not generic for a product category. Exclusion of any of the process elements or the impact categories eliminates the validity of the results

4 Environmental Impact

In 1993, researchers compared the environmental impacts of linoleum, vinyl, wool and synthetic carpets. Thanks to the use of natural raw materials, the researchers concluded that linoleum was clearly the most environmentally compatible floor covering and linoleum's long life offers an important additional advantage. Similar findings were reported in 1995.

- We achieve maximum waste reduction by recycling all linoleum remnants back into the production process.
- At our plant in the Netherlands we expect to reduce the specific energy used per kilogram of product by 15 % within 5 years
- We use no heavy metals or any other incompatible additives, positively impacting repairability
- All of our adhesives are 100 % solvent free and meet all low VOC requirements, optimizing the environmental performance of the entire system.
- We have developed a dry maintenance system, limiting chemical use and waste water disposal.
- Our approach to waste is to recycle as much as possible and to design our processes so that there is less waste to start with. What's left is burnt in an energy-recycling incineration plant or added to landfill refuse sites and allowed to fully biodegrade.

Natural raw materials are only the start of our strong environmental performance. State of the art processes ensure that each production stage causes minimum environmental impact. On average, 12 % of our total capital investments are spent on measures designed to further improve environmental performance.

5 Conclusions

LCA's help you do your job better. They help you identify products that with positively and directly impact on the health and wellbeing of every single person who walks through your front door. As you've seen, selecting green products, those with documented life-cycle assessments, cannot only improve occupant health and facility-wide productivity, but can also offer significant cost reductions, particularly when considering the long-term lifecycle costs of doing business.
